EFFECTS OF ADSORPTION CONSTANT UNCERTAINTY ON CONTAMINANT PLUME MIGRATION: ONE-DIMENSIONAL NUMERICAL STUDIES 2. 1 Abstract This chapter is an update of Criscenti et al. (2002; NUREG CR-6780). In this study, the hydrology and mineralogy of the Naturita uranium mill tailings site in Colorado are used to establish initial conditions and processes to incorporate into a one-dimensional (1-D) reactive-transport model. This model describes adsorption using an electrostatic surface complexation approach. This study is the first to examine variations in reactive-transport model predictions due to uncertainties in the equilibrium constants associated with an electrostatic model for adsorption. This work demonstrates the importance of selecting appropriate adsorption constants when using reactive-transport models to evaluate risk and pollution attenuation at contaminated sites. In our simulations, uranium is removed from mill tailings leachate through adsorption onto smectite, an abundant clay mineral at the Naturita site. Uranium adsorbs to specific surface sites on both the basal planes and edges of the smectite. Because uranium adsorbs predominantly to the aluminum edge surface sites (e) ALOH , we chose to examine uncertainty only in the equilibrium constants associated with these sites. One-hundred pairs of- equilibrium constant (log K) values for the surface species (e) ALO and (e) ALOUO were 2 selected from normal distributions of each log K using the Latin Hypercube Sampling method. For the 1-D simulations, two distinct groups of uranium concentration versus distance profiles can be identified. In the first...
